Introduction

◆ **Threads:**

- Grew up in OS world (processes).
- Evolved into user-level tool.
- Proposed as solution for a variety of problems.
- Every programmer should be a threads programmer?

◆ **Problem: threads are very hard to program.**

◆ **Alternative: events.**

◆ **Claims:**

- For most purposes proposed for threads, events are better.
- Threads should be used only when true CPU concurrency is needed.

What Are Threads?

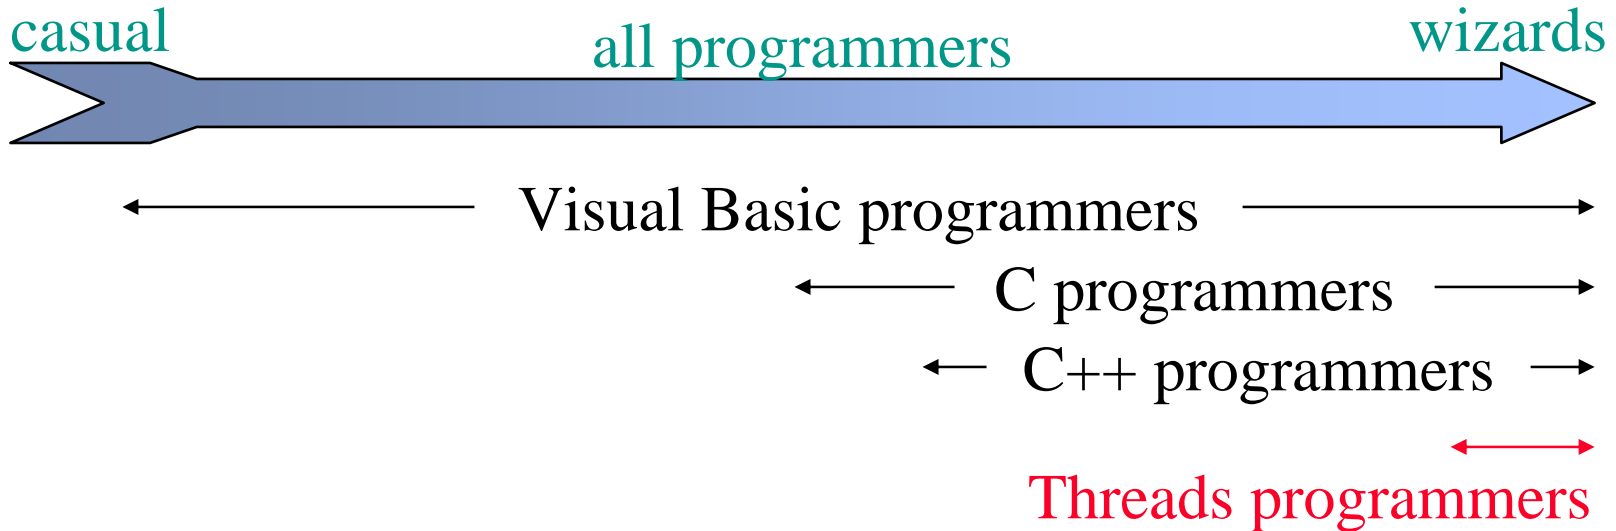

- ◆ **General-purpose solution for managing concurrency.**
- ◆ **Multiple independent execution streams.**
- ◆ **Shared state.**
- ◆ **Pre-emptive scheduling.**
- ◆ **Synchronization (e.g. locks, conditions).**

What Are Threads Used For?

- ◆ **Operating systems:** one kernel thread for each user process.
- ◆ **Scientific applications:** one thread per CPU (solve problems more quickly).
- ◆ **Distributed systems:** process requests concurrently (overlap I/Os).
- ◆ **GUIs:**
 - Threads correspond to user actions; can service display during long-running computations.
 - Multimedia, animations.

What's Wrong With Threads?

- ◆ Too hard for most programmers to use.
- ◆ Even for experts, development is painful.

Why Threads Are Hard

◆ Synchronization:

- Must coordinate access to shared data with locks.
- Forget a lock? Corrupted data.

◆ Deadlock:

- Circular dependencies among locks.
- Each process waits for some other process: system hangs.

Why Threads Are Hard, cont'd

- ◆ **Hard to debug:** data dependencies, timing dependencies.
- ◆ **Threads break abstraction:** can't design modules independently.
- ◆ **Callbacks don't work with locks.**

Why Threads Are Hard, cont'd

- ◆ **Achieving good performance is hard:**
 - Simple locking (e.g. monitors) yields low concurrency.
 - Fine-grain locking increases complexity, reduces performance in normal case.
 - OSes limit performance (scheduling, context switches).
- ◆ **Threads not well supported:**
 - Hard to port threaded code (PCs? Macs?).
 - Standard libraries not thread-safe.
 - Kernel calls, window systems not multi-threaded.
 - Few debugging tools (LockLint, debuggers?).
- ◆ **Often don't want concurrency anyway (e.g. window events).**

Event-Driven Programming

- ◆ **One execution stream: no CPU concurrency.**
- ◆ **Register interest in events (callbacks).**
- ◆ **Event loop waits for events, invokes handlers.**
- ◆ **No preemption of event handlers.**
- ◆ **Handlers generally short-lived.**

What Are Events Used For?

◆ Mostly **GUIs**:

- One handler for each event (press button, invoke menu entry, etc.).
- Handler implements behavior (undo, delete file, etc.).

◆ **Distributed systems**:

- One handler for each source of input (socket, etc.).
- Handler processes incoming request, sends response.
- Event-driven I/O for I/O overlap.

Problems With Events

- ◆ **Long-running handlers** make application non-responsive.
 - Fork off subprocesses for long-running things (e.g. multimedia), use events to find out when done.
 - Break up handlers (e.g. event-driven I/O).
 - Periodically call event loop in handler (reenetrancy adds complexity).
- ◆ Can't maintain **local state** across events (handler must return).
- ◆ **No CPU concurrency** (not suitable for scientific apps).
- ◆ Event-driven I/O not always well supported (e.g. poor write buffering).

Events vs. Threads

- ◆ **Events avoid concurrency as much as possible, threads embrace:**
 - Easy to get started with events: no concurrency, no preemption, no synchronization, no deadlock.
 - Use complicated techniques only for unusual cases.
 - With threads, even the simplest application faces the full complexity.
- ◆ **Debugging easier with events:**
 - Timing dependencies only related to events, not to internal scheduling.
 - Problems easier to track down: slow response to button vs. corrupted memory.

Events vs. Threads, cont'd

- ◆ **Events faster than threads on single CPU:**
 - No locking overheads.
 - No context switching.
- ◆ **Events more portable than threads.**
- ◆ **Threads provide true concurrency:**
 - Can have long-running stateful handlers without freezes.
 - Scalable performance on multiple CPUs.

Should You Abandon Threads?

- ◆ **No:** important for high-end servers (e.g. databases).
- ◆ **But, avoid threads wherever possible:**
 - Use events, not threads, for GUIs, distributed systems, low-end servers.
 - Only use threads where true CPU concurrency is needed.
 - Where threads needed, isolate usage in threaded application kernel: keep most of code single-threaded.

Conclusions

- ◆ **Concurrency is fundamentally hard; avoid whenever possible.**
- ◆ **Threads more powerful than events, but power is rarely needed.**
- ◆ **Threads much harder to program than events; for experts only.**
- ◆ **Use events as primary development tool (both GUIs and distributed systems).**
- ◆ **Use threads only for performance-critical kernels.**
